Outline

• Introduction
• Single-atom levels in a random potential
• Weakly repulsive gas in a random potential
• Weakly repulsive gas in a harmonic trap
• Conclusions

Purposes: Semiquantitative analysis of the phase states of the gas in a box
The size and shape of the atomic cloud in a harmonic trap
Introduction

Bose-Einstein-condensation: finite part of atoms in the state with minimal energy.

Examples: Superfluid $^4\text{He}$, laser cooled atoms in a trap

Disorder: Superfluid He in a porous media: J. Reppy and coworkers, J. Low Temp. Phys. 87, 205 (1992) and references therein: Breakdown of superfluidity at strong disorder
Bose-Einstein Condensate in a Random Potential

J. E. Lye, L. Fallani, M. Modugno, D. S. Wiersma, C. Fort, and M. Inguscio

FIG. 1 (color online). (a) Optical setup for both the speckle potential and the imaging beam for the BEC. The axial direction of the magnetic trap is in the vertical direction of the figure (b) 3D representation of the speckle potential (left) and its Fourier transform (right). The dotted lines correspond to a length scale of about 10 μm in the axial direction.

FIG. 2 (color online). (a) Density profile of the BEC after 28 ms of expansion from the combined magnetic and speckle potential for varying speckle potential intensities $V_s$ (indicated in bottom part). To demonstrate that the transfer to the speckle is adiabatic (b) shows the density profiles with (i) no speckle potential, (ii) when the speckle potential is abruptly switched off, and (iii) when it is adiabatically ramped off. (c) Dipole oscillations in the combined magnetic and speckle potential for varying $V_s$. 
Theoretical works:

Corrections to the Bogolyubov theory caused by a weak disorder

K. Huang and H.F. Meng, Phys. Rev. Lett. 69, 644 (1992);

Possible Bose-glass state

Spin model, transition from the normal state to superfluid

Bose Hubbard model, scaling near transition point

One-dimensional Hubbard model
Single atom levels in a random potential

Ideal Bose gas

Ground state

Non-ergodic ground state or quenched distribution dependent on the cooling speed
Gaussian white noise

\[ \langle U(x)U(x') \rangle = \kappa^2 \delta(x - x') \]

Independent probability distribution in each point:

\[
dW[U(x), \Omega] = \exp \left[ -\frac{1}{2\kappa^2} \int_\Omega U^2(x) d\Omega \right] \prod_{x \in \Omega} \frac{\sqrt{\Delta\Omega} dU(x)}{\sqrt{2\pi}\kappa}
\]

Energy levels in the random potential:

\[
-\frac{\hbar^2}{2m} \nabla^2 \psi + U(x)\psi = E[U]\psi
\]
Density of states:

$$\nu(E, \Omega) = \int \delta(E - E[U]) dW[U(x), \Omega]$$

$$dW[U(x), \Omega] = \exp \left[ -\frac{1}{2\kappa^2} \int_\Omega U^2(x) \, d\Omega \right] \prod_{x \in \Omega} \frac{\sqrt{\Delta \Omega} dU(x)}{\sqrt{2\pi\kappa}}$$

Deep levels:

$$E < 0; \quad |E| \leq E_{\xi} = \frac{m^2 \kappa^4}{\hbar^2}$$

Minimize \( \int_\Omega U^2(x) \, d\Omega \) at fixed \( E[U] \)

The optimal fluctuation potential well is spherically symmetric. The optimal level is the only bound state in this well.

$$U(x) = \lambda |\psi(x)|^2$$

Ginzburg-Landau equation

Fluctuation potential well has the same linear size as the wave function
Semiquantitative approach

Typical potential well with a deep level

All calculations for 3d space

Balance of kinetic and potential energy:

\[ |E| - |U| \frac{\hbar^2}{2mR^2} \]

Probability to find energy less than \(-E\) or part of space occupied by the potential wells with the size of the quantum state less than \(R\):

\[ P(R) = \exp \left( -\frac{U^2\Omega}{2\kappa^2} \right) = \exp \left( -\frac{\pi \hbar^4}{6m^2\kappa^2 R} \right) \]

Explanation:

\[ \int_{\Omega} U^2(x) d\Omega \approx U^2\Omega \quad \Omega \approx \frac{4}{3} \pi R^3 \]

Larkin length:

\[ \xi = \frac{\pi \hbar^4}{6m^2\kappa^2} \]

Probability:

\[ P(R) = \exp \left( -\frac{\xi}{R} \right) \]

Preexponent: inessential

Valid at \(R \gg \xi\)

\[ P(\xi) \ll 1 \quad \xi = E_\xi = \frac{\hbar^2}{2m\xi} \]

Levels of Larkin size percolate

June 22-26, 2008

Landau Memorial Conference
Density of cells with the quantum states of the size $R$

$$n_w(R) = R^{-3} \exp \left( -\frac{\mathcal{Q}}{R} \right)$$

Average distance between the states of the size $R$:

$$d(R) = \left[ n_w(R) \right]^{-1/3} = R \exp \left( \frac{\mathcal{Q}}{3R} \right)$$

Tunneling amplitude between neighboring states of the size $R$

$$t(R) = \exp \left( -\sqrt{\frac{2mU}{\hbar}} d(R) \right) = \exp \left[ -\exp \left( \frac{\mathcal{Q}}{3R} \right) \right]$$
Weakly repulsive gas in a random potential

\[ H = \sum_p \frac{p^2}{2m} a_p^\dagger a_p + g \int (\psi^\dagger \psi)^2 \ d\Omega + \int U \psi^\dagger \psi \ d\Omega \]

Due to repulsion atoms are distributed between different wells

Repulsion restores ergodicity
Repulsion energy per particle is \( g n_p(R) \)

\[ n_p(R) \] is the density of particles in the well of the size \( R \)

Let the potential wells with the radii up to \( R \) are filled. Then:

\[ n_p(R) = \frac{n}{n_w(R)} \frac{3}{4\pi R^3} = \frac{3n}{4\pi} \exp\left(\frac{\xi}{R}\right) \]

**Number of particles per well**

Energy per particle:

\[ \mu = g n_p(R) - \frac{\hbar^2}{2mR^2} \]

**Energy of the random well**

Minimization over \( R \):

\[ R(n) = \frac{\xi}{\ln \frac{n_c}{n}} \quad n_c = \left(3\xi^2 a\right)^{-1} \]

**Typical radius reached**

**Critical density**

\[ g = \frac{4\pi\hbar^2 a}{m} \]

**Scattering length**

Chemical potential:

\[ \mu = -\frac{\hbar^2}{2m\xi^2} \left(\ln \frac{n_c}{n}\right)^2 = -\xi \left(\ln \frac{n_c}{n}\right)^2 \]
Maximal size of the well occupied by atoms:

\[ R(n) = \mathcal{L} \ln \frac{n_c}{n} \quad \quad n_c = \left(3\mathcal{L}^2 a\right)^{-1} \]

Distance between occupied wells:

\[ r(n) = \mathcal{L} \left(\frac{n_c}{n}\right)^{1/3} \ln \frac{n_c}{n} - R(n) \]

Tunneling amplitude between wells:

\[ t(n) = \exp\left[-\left(\frac{n_c}{n}\right)^{1/3}\right] \]

Number of particles per well:

\[ \mathcal{N} = \frac{\mathcal{L}}{3a \ln \left(\frac{n_c}{n}\right)} \]
Partial conclusions

At $n$ much less than $n_c$ different wells are exponentially weakly coupled and have well defined number of particles. Therefore the phase in each well is uncertain. Random singlet. No coherence, no superfluidity, Bose glass?

At $n$ approaching $n_c$ distances between the wells become of the same order of magnitude as their radius, the overlapping factor $t$ becomes of the order of 1. Strong growth of the correlation between phases.

At $n=n_c$ quantum phase transition from disordered singlet state to disordered superfluid. Scaling near transition was studied by Matthew Fisher et al. Marginal dimensionality is 1 (Giamarchi and Schulz). Is it the same transition?

Model description: random quantum $XY$-model:

$$H_{xy} = \sum_j K_j \left( N_j - \bar{N}_j \right)^2 - \sum_{ij} t_{ij} \cos(\varphi_i - \varphi_j)$$

$n \ll n_c$ -- almost homogeneous superfluid, small corrections to Bogolyubov formulae from disorder (Huang and Meng)
Giamarchi-Schulz phase diagram

Transition at weak interaction (PN)
Transition at strong interaction (Giamarchi and Schulz)
Weakly repulsive gas in a harmonic trap

Single particle states in a trap

\[ V(x) = \frac{m\omega^2 x^2}{2} \]

Energy levels:

\[ E_n = \left( n + \frac{1}{2} \right) \hbar \omega \]

\[ \ell = \sqrt{\frac{\hbar}{m\omega}} \quad \text{Magnetic length} \]

Weakly repulsive \( N \) particles in a harmonic trap, no disorder, form a spherical cloud of the size \( R \)

\[ E(R, N) = N \left( \frac{\hbar^2}{2mR^2} + \frac{m\omega^2 R^2}{2} + gn \right) \]

\[ n = \frac{3N}{4\pi R^3}; \quad g = \frac{4\pi \hbar^2 a}{m} \]

\( \ell \)

\( x \)

\( L \)

\( \ell \)

\( x \)
\[ E(L, N) = N \frac{\hbar^2}{2m} \left( \frac{1}{L^2} + \frac{L^2}{\ell^4} + \frac{3Na}{L^3} \right) \]

Must be minimized over \( R \)

Weak interaction \( 3Na \square \ell \Rightarrow L = \ell \)

Strong interaction \( 3Na \square \ell \Rightarrow L = \left( \frac{9}{2} Na \ell^4 \right)^{1/5} \)

Thomas-Fermi approximation
Disorder potential \[ \langle U(x)U(x') \rangle = \kappa^2 \delta(x-x') \]

\[ \mathcal{L} \ll \ell \quad \text{-- weak disorder; small corrections to the previous results} \]

**Strong disorder, weak interaction**

\[ a \ll Na \ll \mathcal{L} \ll \ell \quad \text{-- non-ergodic situation; in equilibrium all particles occupy a single random potential well with minimal energy} \]

Size of the cloud is determined by the energy balance:

\[ \mathcal{E}_\mathcal{L} = \frac{\hbar^2}{2m\mathcal{L}^2} \cdot \frac{m\omega^2 L^2}{2} \quad \Rightarrow \quad L = \frac{\ell^2}{\mathcal{L}} \]

Energy of disorder (logarithmic accuracy)

Energy of trap

Typical size of the well:

\[ R = \frac{\mathcal{L}}{6 \ln \left( \ell / \mathcal{L} \right)} \]
Strong disorder, moderately strong interaction: \( a \square \ \mathcal{L} \square \ \text{Na} \square \ \ell \)

**Ergodic situation**

\[ N \square \left( \ell^6 / \mathcal{L}^5 a \right) \quad \text{or} \quad \Gamma = \ell^6 / \left( 3 \mathcal{L}^5 a N \right) \square 1 \]

Multiple random potential wells (fragmentation). Average particle density \( n \) is a slow function of coordinate \( r \)

\[
\mu = gn_p(r) - \frac{\hbar^2}{2mR^2(r)} + \frac{m\omega^2 r^2}{2} \approx -\mathcal{E}_\xi \ln^2 \frac{n_c}{n(r)} + \frac{m\omega^2 r^2}{2} 
\]

\[
n(r) = n_c \exp \left( -\sqrt{\frac{\mathcal{L}^2 r^2}{\ell^4} - \frac{\mu}{\mathcal{E}_\xi}} \right) \approx n_c \exp \left( -\sqrt{-\mu / \mathcal{E}_\xi} \right) \exp \left( -\frac{\mathcal{L}^2 r^2}{2\ell^4 \sqrt{-\mu / \mathcal{E}_\xi}} \right) 
\]

\[
R = \mathcal{L} / \ln \Gamma \quad d = \mathcal{L} \Gamma^{1/3} / \ln \Gamma \quad L = \left( \ell^2 / \mathcal{L} \right) \sqrt{\ln \Gamma}
\]

No coherence, random singlet or Bose glass

Counter-intuitive dependence of \( L \) on \( N \)
\[ N \ll \left( \frac{\ell^6}{\xi^5 a} \right) \quad \text{or} \quad \Gamma = \ell^6 / \left( 3 \xi^5 a N \right)  \]

Small corrections of the order of $\frac{\ell^6}{\xi^5 a}$ to the state without disorder.

Superfluid

Phase transition line: \( \Gamma = 1 \)

Distribution of momentum in fragmented state

\[ p_0 = \left( \frac{\hbar}{\xi} \right) \ln \Gamma \]

Number of fragments

\[ N_F \ll \frac{12 Na}{\xi} \left( \ln \Gamma \right)^{9/2} \]
Phase diagram

\[ L \propto \left( N_a \ell^4 \right)^{1/5} \]

Thomas-Fermi, superfluid

Ideal gas, weak disorder

Fragmented state
No coherence

\[ R \propto \mathcal{L}/\ln \Gamma \]

Non-ergodic state

\[ R = \frac{\mathcal{L}}{6 \ln (\ell/\mathcal{L})} \]
Conclusions

• We describe properties of weakly interacting Bose gas in a random Gaussian potential with zero correlation length and approach (but not reach) the superfluid transition line.
• The character and quantitative characteristics of weakly interacting Bose-gas in such potential can be described in terms of two characteristic lengths: the Larkin length characterizing disorder and the scattering amplitude.
• The ground state of ideal Bose gas in random potential in thermodynamic limit is non-ergodic.
• Even a weak interaction changes drastically the property of the ground state.
• At average particle density much less than a critical one, the Bose particles occupy deep potential wells and exponentially weakly tunnel to other wells. The number of particles in each well is defined, but phases are uncertain. It is a disordered singlet state.
• At average particle density equal to the critical value determined by interaction and disorder, the transition to the inhomogeneous superfluid proceeds.
• In a trap, at sufficiently strong disorder and weak interaction (small value of the product of number of particles and the scattering amplitude), the ground state is non-ergodic.
• Starting from a critical value of the above mentioned product the state becomes ergodic and fragmented. There is no coherence between fragments.
• At a fixed disorder the growing number of particles leads to transition from disordered singlet to superfluid state.
• In terms of 1d theory by Giamarchi and Schulz we describe the approach to the phase transition at weak interaction, which they conjectured but could not treat quantitatively.
What did not enter to this presentation

- Two- and one-dimensional traps
- Bose-gases with attraction in a disordered trap
- Fermi-gases
- Dipolar oscillations of the clouds in traps
- Single-connected states at very large number of particles due to the trap potential
- Correlated noise with correlation length larger than Larkin length
